Supervised learning

Spam filtering example

	and	viagra	the	of	nigeria	y
x^1	1	1	0	1	1	+1
x^2	0	0	1	1	0	-1
x^3	0	1	1	0	0	+1
x^4	1	0	0	1	0	-1
x^5	1	0	1	0	1	+1
x^6	1	0	1	1	0	-1

- Training set ($X = [x^1, x^2, \dots, x^n], y=[y_1, y_2, \dots, y_n]$)
 - x^i in $X = R^d$: instance i with d dimensional features
 - y_i in $Y = \{-1, 1\}$: instance i is spam or ham?
- Good **feature representation** is of utmost importance

Batch vs. Online

- Batch learning
 - Interested in performance on **test** set X'
 - Training set (X, y) is just a means
 - Statistical assumption on X and X'
- Online learning
 - Data **comes one by one** (streaming)
 - Need to predict y before knowing its true value
 - Interested in making as few mistakes as possible
 - “Friendliness” of the sequence $(x^1, y_1), (x^2, y_2), \dots$
- Online to Batch conversion

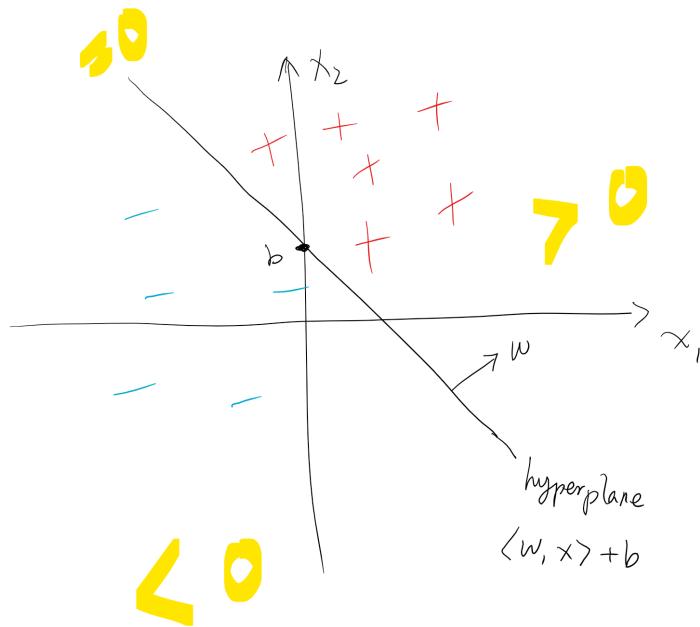

Linear threshold function

- Find (w, b) such that for all i :

$$y_i = \text{sign}(\langle w, x^i \rangle + b)$$

- w in R^d : weight vector for the **separating hyperplane**
- b in R : offset (threshold, bias) of the separating hyperplane
- sign: thresholding function

$$\text{sign}(t) = \begin{cases} 1, & t > 0 \\ -1, & t \leq 0 \end{cases}$$

Simplification

$$\langle \mathbf{w}, \mathbf{x} \rangle + b = \left\langle \begin{pmatrix} \mathbf{w} \\ b \end{pmatrix}, \begin{pmatrix} \mathbf{x} \\ 1 \end{pmatrix} \right\rangle$$

- Padding constant 1 to the end of each \mathbf{x}

Also denote as $\mathbf{w} \dots$

$$y \cdot \text{sign}(\langle \mathbf{w}, \mathbf{x} \rangle) = \text{sign}(\langle \mathbf{w}, y\mathbf{x} \rangle)$$

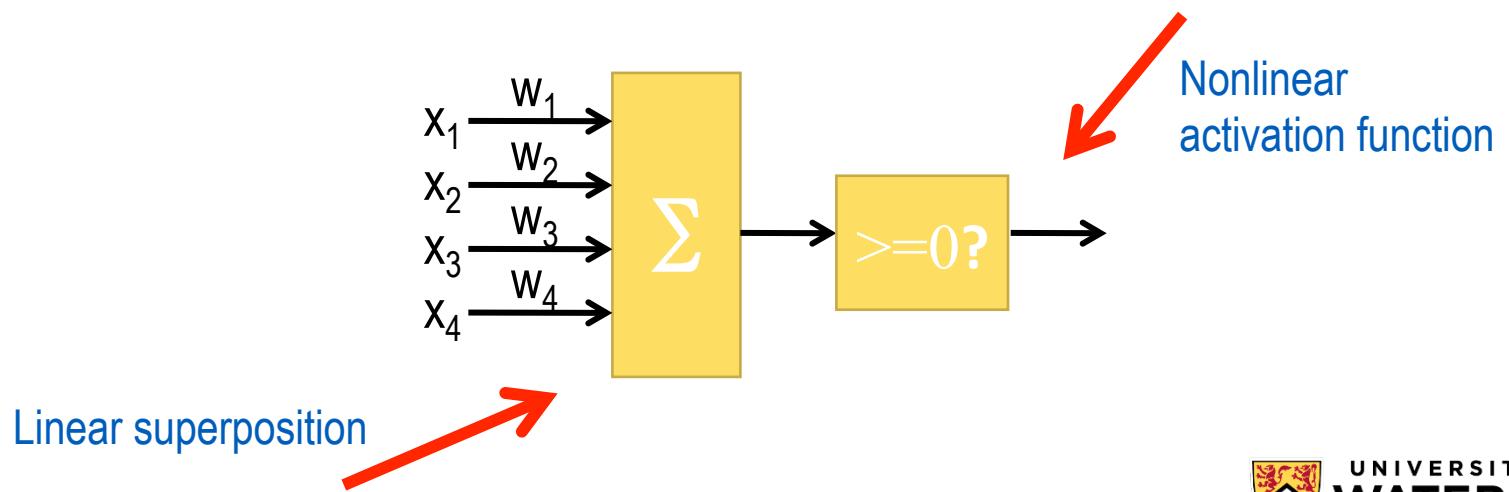

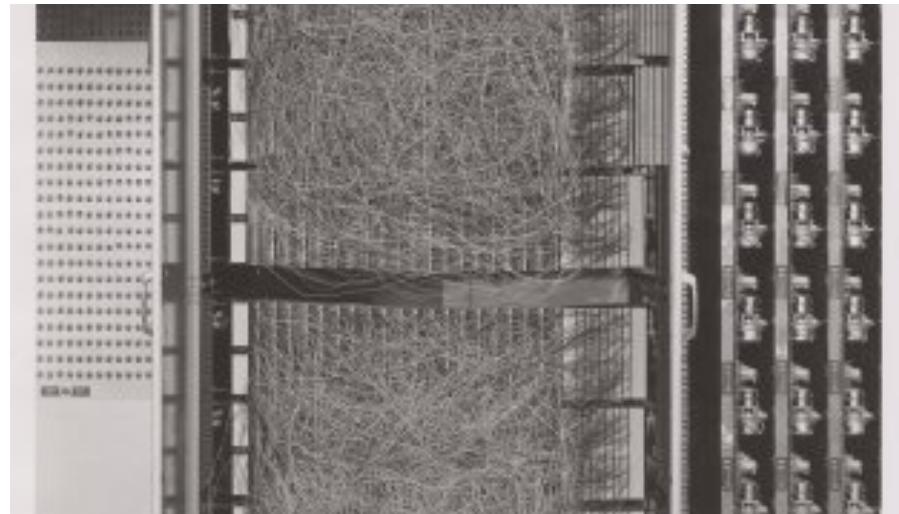

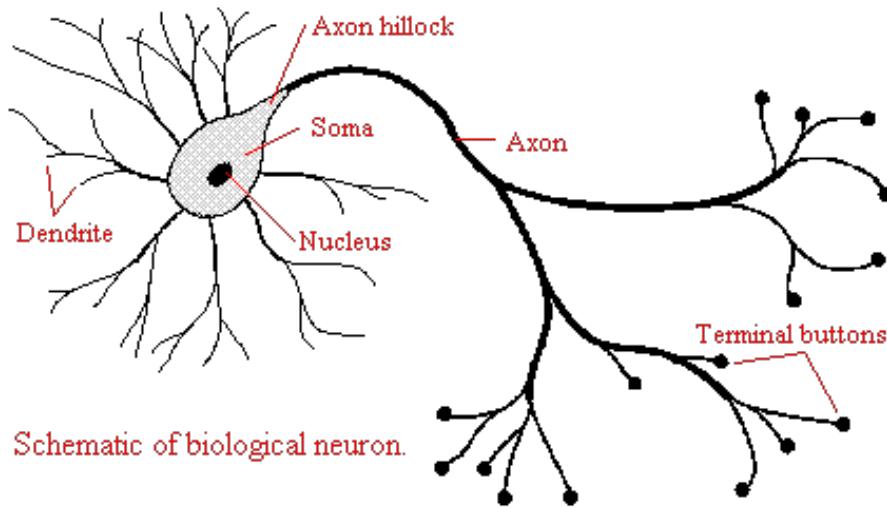

- Pre-multiply each \mathbf{x} with its label y

$$A = [\mathbf{a}^1, \dots, \mathbf{a}^n]$$

- Find \mathbf{w} such that $A^T \mathbf{w} > 0$

$$\mathbf{a}^i = \begin{pmatrix} y_i \mathbf{x}^i \\ y_i \end{pmatrix}$$

Perceptron [Rosenblatt'58]

The perceptron algorithm

Algorithm 1: The perceptron algorithm (Rosenblatt 1958)

Input: $A \in \mathbb{R}^{(d+1) \times n}$, threshold $\delta \geq 0$, initialize $w_0 \in \mathbb{R}^{d+1}$ arbitrarily

```
1 repeat
2   select some column a of A;
3   if  $\langle a, w_t \rangle \leq \delta$  then
4      $w_{t+1} = w_t + a$ ;                                // update only when making a mistake
5      $t \leftarrow t + 1$ 
6 until convergence;
```

- Typically $\delta = 0$, $w_0 = 0$
 - $\langle a, w \rangle = y(\langle x, w \rangle + b) < 0$ iff $y \neq \text{sign}(\langle x, w \rangle + b)$
- **Lazy** update: if it ain't broke, don't fix it

$$\langle a, w_{t+1} \rangle = \langle a, w_t + a \rangle = \langle a, w_t \rangle + \|a\|_2^2 > \langle a, w_t \rangle.$$

Does it work?

	and	viagra	the	of	nigeria	y
x^1	1	1	0	1	1	+1
x^2	0	0	1	1	0	-1
x^3	0	1	1	0	0	+1
x^4	1	0	0	1	0	-1
x^5	1	0	1	0	1	+1
x^6	1	0	1	1	0	-1

- $w_0 = [0, 0, 0, 0, 0]$, $b_0 = 0$, pred on x^1 undefined
- $w_1 = [1, 1, 0, 1, 1]$, $b_1 = 1$, pred 1 on x^2 , wrong

$\mathbf{w} \leftarrow \mathbf{w} + y\mathbf{x}$ • $w_2 = [1, 1, -1, 0, 1]$, $b_2 = 0$, pred on x^3 undefined

$b \leftarrow b + y$ • $w_3 = [1, 2, 0, 0, 1]$, $b_3 = 1$, pred 1 on x^4 , wrong
 • $w_4 = [0, 2, 0, -1, 1]$, $b_4 = 0$, pred 1 on x^5 , correct
 • $w_4 = [0, 2, 0, -1, 1]$, $b_4 = 0$, pred -1 on x^6 , correct

Perceptron Convergence Theorem

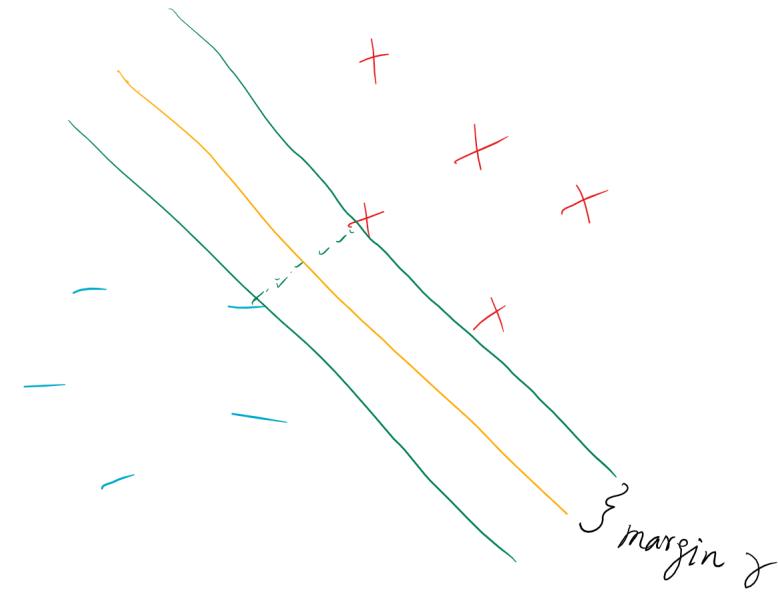

Theorem (Block'62; Novikoff'62). Assume there exists some \mathbf{w} such that $\mathbf{A}^T \mathbf{w} > 0$, then the perceptron algorithm converges to some \mathbf{w}^* . If each column of \mathbf{A} is selected indefinitely often, then $\mathbf{A}^T \mathbf{w}^* > \delta$.

Corollary. Let $\delta = 0$ and $\mathbf{w}_0 = \mathbf{0}$. Then perceptron converges after at most $(R/\gamma)^2$ steps, where

$$R = \max_i \|A_{\cdot i}\|_2, \quad \gamma = \max_{\mathbf{w}: \|\mathbf{w}\|_2 \leq 1} \min_i \langle \mathbf{w}, A_{\cdot i} \rangle$$

The Margin

$$\begin{aligned}
 \min_{\mathbf{w}^*: A^\top \mathbf{w}^* \geq \gamma \mathbf{1}} \frac{\|\mathbf{w}^*\|_2^2}{\gamma^2} &= \min_{\mathbf{w}: A^\top \mathbf{w} \geq \mathbf{1}} \|\mathbf{w}\|_2^2 \\
 &= \min_{(\mathbf{w}, t): \|\mathbf{w}\|_2 \leq t, A^\top \mathbf{w} \geq \mathbf{1}} t^2 \\
 &= \min_{(\mathbf{w}, t): \|\mathbf{w}\|_2 \leq 1, A^\top \mathbf{w} \geq \frac{1}{t} \mathbf{1}} t^2 \\
 &= \min_{\mathbf{w}: \|\mathbf{w}\|_2 \leq 1, A^\top \mathbf{w} > 0} \frac{1}{\min_{\mathbf{a} \in A} \langle \mathbf{a}, \mathbf{w} \rangle^2} \\
 &= \underbrace{\left[\frac{1}{\max_{\mathbf{w}: \|\mathbf{w}\|_2 \leq 1} \min_{\mathbf{a} \in A} \langle \mathbf{a}, \mathbf{w} \rangle} \right]^2}_{\text{the margin } \gamma}
 \end{aligned}$$

What does the bound mean?

Corollary. Let $\delta = 0$ and $\mathbf{w}_0 = \mathbf{0}$. Then perceptron converges after at most $(R/\gamma)^2$ steps, where

$$R = \max_i \|A_{:i}\|_2, \quad \gamma = \max_{\mathbf{w}: \|\mathbf{w}\|_2 \leq 1} \min_i \langle \mathbf{w}, A_{:i} \rangle$$

- Treating R and γ as constants, then
of mistakes independent of n and d !
- Otherwise may need exponential time...
- Can we **improve** the bound?

But

- ✓ The larger the margin, the faster perceptron converges
- ✗ But perceptron stops at an arbitrary linear separator...

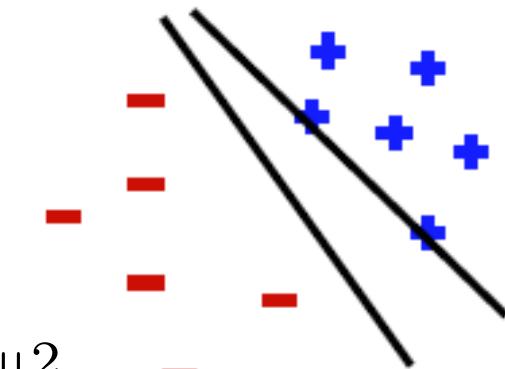

- Which one do you prefer?

$$\min_{A^\top \mathbf{w} \geq 1} \frac{1}{2} \|\mathbf{w}\|_2^2 \approx \min_{y_i(\langle \mathbf{w}, \mathbf{x}^i \rangle + b) \geq 1} \frac{1}{2} \|\mathbf{w}\|_2^2$$

Support vector machines

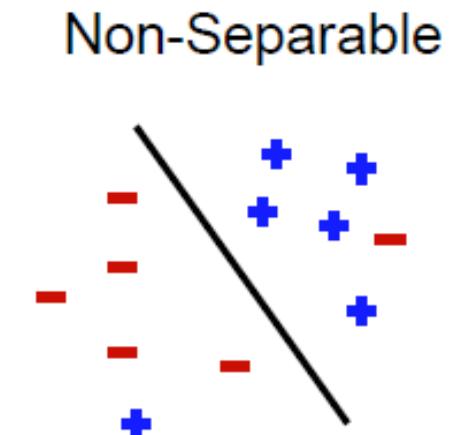

Separable

What if non-separable?

- Find a better feature representation
- Use a deeper model
- **Soft** margin

$$\forall \mathbf{w}^*, \forall \gamma > 0, \text{ and } \forall \mathbf{a} \in A : \langle \mathbf{a}, \mathbf{w}^* \rangle \geq \gamma - (\gamma - \langle \mathbf{a}, \mathbf{w}^* \rangle)_+$$

Perceptron Boundedness Theorem

- Perceptron convergence requires the **existence** of a separating hyperplane
 - how to check this assumption in practice?
 - What if it fails? (trust me, it will)

Theorem (Minsky and Papert'67; Block and Levin'70).

The iterates of the perceptron algorithm are always bounded. In particular, if there is no separating hyperplane, then perceptron cycles.

“...proof of this theorem is complicated and obscure. So are the other proofs we have since seen...” --- Minsky and Papert, 1987

When to stop perceptron?

- Online learning: never
- Batch learning
 - Maximum number of iteration reached or run out of time
 - Training error stops changing
 - Validation error stops decreasing
 - Weights stopped changing much, if using a diminishing step size η_t , i.e., $w_{t+1} \leftarrow w_t + \eta_t y_i x^i$

Multiclass Perceptron

- One vs. all
 - Class c as positive
 - All other classes as negative
 - Highest activation wins: $\text{pred} = \operatorname{argmax}_c \mathbf{w}_c^T \mathbf{x}$
- One vs. one
 - Class c as positive
 - Class c' as negative
 - Voting

Winnow (Littlestone'88)

Algorithm 2: The Winnow algorithm (Littlestone 1988)

```
Input:  $A \in \mathbb{R}^{d' \times n}$ , threshold  $\delta \geq 0$ , step size  $\eta > 0$ , initialize  $w_0 \in \text{int}\Delta_{d'-1}$ 
1 repeat
2   select some column  $a$  of  $A$ ;
3   if  $\langle a, w_t \rangle \leq \delta$  then
4      $w_{t+1} = w_t \odot \exp(\eta a)$ ;           // update only when making a mistake
5      $w_{t+1} \leftarrow w_{t+1} / \|w_{t+1}\|_1$ ;    // normalize
6      $t \leftarrow t + 1$ 
7 until convergence;
```

- Multiplicative vs. additive

Theorem (Littlestone'88). Assume there exists some nonnegative w such that $A^T w > 0$, then winnow converges to some w^* . If each column of A is selected indefinitely often, then $A^T w^* > \delta$.

Another example: pricing

- Selling a product Z to user x with price $y = f(x, w)$
- If y is too high, user won't buy, update w
- If y is acceptable, user buy [update w]
- How to measure our performance?

Linear regression

- Perceptron is a **linear** rule for **classification**
 - y in a finite set, e.g., $\{+1, -1\}$

- What if y can be any real number?

- Known as **regression**
 - Again, there is a linear rule

$$\min_{\mathbf{w} \in \mathbb{R}^d} \frac{1}{2} \|\mathbf{X}\mathbf{w} - \mathbf{y}\|_2^2 + \lambda \|\mathbf{w}\|_2^2$$

- Regularization to avoid overfitting
- Cross-validation to select hyperparameter

Questions?
